## Preface

Tuna fisheries assessment reports provide current information on the tuna fisheries of the western and central Pacific Ocean (WCPO) and the fish stocks (mainly tuna) that are impacted by them. The information provided in this report is summary in nature, but a list of references (mostly accessible via the internet) is included for those seeking further details. This report is a smart PDF so if you click on a reference within the document it will take you to the figure/section; to return to the page you were on, press alt and the left arrow key.

This report focuses on the primary tuna stocks targeted by the main WCPO industrial fisheries - skipjack (Katsuwonus pelamis), yellowfin (Thunnus albacares), bigeye (T. obesus) and South Pacific albacore tuna (T. alalunga).

The report is divided into three parts: the first section provides an overview of the fishery, with emphasis on developments over the past few years; the second summarises the most recent information on the status of the stocks; and the third summarises information concerning the interaction between the tuna fisheries, other associated and dependent species and their environment. The data used in compiling the report are those which were available to the Oceanic Fisheries Programme (OFP) at the time of publication, and are subject to change as improvements continue to be made to recent and historical catch statistics from the region. The fisheries statistics presented will usually be complete through the end of the year prior to publication. However, some minor revisions to statistics occasionally may be made for recent years. The stock assessment information presented is the most recent available at the time of publication.

Inquiries regarding this report or other aspects of the work programme of the OFP should be directed to:

## 1 The western and central Pacific tuna fishery

The tuna fisheries in the western and central Pacific Ocean (WCPO), encompassed by the Western and Central Pacific Fisheries Commission Convention Area (WCPFC-CA) (Figure 1), are diverse, ranging from small-scale, artisanal operations in the coastal waters of Pacific states, to large-scale, industrial purse seine, pole-and-line and longline operations in the exclusive economic zones (EEZs) of Pacific states and in international waters (high seas). The main species targeted by these fisheries are skipjack tuna (Katsuwonus pelamis), yellowfin tuna (Thunnus albacares), bigeye tuna ( $T$. obesus) and albacore tuna ( $T$. alalunga).

The current fishery characterisation includes updates to historical data, which show that 2019 was the highest catch year in history, with catches of the four target tuna species just under 3 million tonnes ( t ). We expect revisions to the 2019 catch estimates in next year's report, as estimates in the most recent year are preliminary.

Annual total catch of the four main tuna species in the WCPFC-CA increased steadily during the 1980s as the purse seine fleet expanded, and remained relatively stable during most of the 1990s until a sharp increase in catch in 1998. Since then, there has been an upward trend in total tuna catch, primarily due to increases in purse seine catch, with some stabilisation since 2012 (Figure 2 and Table 1). The provisional total WCPFC-CA tuna catch for 2019 was estimated at 2,997,309t - a record catch. In 2019, the purse seine fishery accounted for an estimated $2,108,012 \mathrm{t}$ ( $70 \%$ of the total catch), a record catch for this fishery. The pole-and-line fishery landed an estimated $191,135 \mathrm{t}$ ( $6 \%$ of the catch - a drop from the highest value $(415,016 \mathrm{t})$, recorded in 1984, a time of much greater pole-and-line vessel participation as discussed below). The longline fishery in 2019 accounted for an estimated 279,015t ( $9 \%$ of the catch) - a drop from the highest value $(284,849$ t $)$, recorded in 2004 . Troll gear accounted for $<1 \%$ of the total catch $(8,116 \mathrm{t})$, a drop from the highest value $(25,845 \mathrm{t})$, recorded in 2000 . The remaining $14 \%(411,031 \mathrm{t})$ was taken by a variety of artisanal gear, mostly in eastern Indonesia, the Philippines and Vietnam, which is a slight drop from the highest value (412,680t), recorded in 2018. The WCPFC-CA tuna catch for 2019 represented $81 \%$ of the total Pacific Ocean catch (3,696,933t) and $55 \%$ of the global tuna catch (the provisional estimate for 2019 being 5,443,488t, a record global catch).

The 2019 WCPFC-CA catch of skipjack ( $2,045,970 t-68 \%$ of the total catch) was a record catch, and an increase of $10 \%$ from 2018 (Table 2). The WCPFC-CA yellowfin catch for 2019 (696,797t - $23 \%$ of the total catch) is around $17,000 \mathrm{t}$ lower than the highest value ( $713,773 \mathrm{t}$ ), recorded in 2017 . The WCPFC-CA bigeye catch for 2019 ( $135,442 \mathrm{t}-5 \%$ of the total catch) was a drop from the highest value $(181,707 \mathrm{t})$, recorded in 2004, and a $10 \%$ decrease over the 2018 catch. The WCPFC-CA albacore catch for 2019 $(119,100 t-4 \%$ of the total catch) was a drop from the highest value ( $148,051 \mathrm{t}$ ), recorded in 2002 , and a $7 \%$ increase over the 2018 catch. As there are separate assessments for South Pacific albacore and North Pacific albacore, the WCPFC-CA catch of albacore (Table 2) is further divided into two summary tables (Table 7 and Table 8). South Pacific albacore in the WCPFC-CA, assessed by SPC ${ }^{1}$, totalled a 2019 catch of $69,301 \mathrm{t}$ which is $4 \%$ greater than the average of the previous five years, but $11 \%$ lower than the highest value $(77,884 \mathrm{t})$, recorded in 2010 . The albacore tuna catch in the WCPFC-CA north of the equator was 49,696 t in 2019 , which is $2 \%$ greater than the average of the past five years, but less than half the highest catch of $104,233 \mathrm{t}$, taken in 1976; the International Scientific Committee for Tuna and Tuna-Like Species in the North Pacific Ocean (ISC) is responsible for conducting assessments ${ }^{2}$ of albacore tuna in the North Pacific Ocean.

Several indices of annual fishing effort for the major gears employed in the commercial tuna fisheries are summarised in Table 3, Figure 3 (purse seine), Figure 4 (longline) and Figure 5 (pole-and-line). For the purse seine fleet, excluding the Indonesian, Philippine and Vietnamese domestic vessels, the number of active vessels peaked in 2014 and 2015 at 313. The percentage of purse seiners flagged to Pacific Island states has steadily increased from 0 as late as 1979 to a high of $45 \%$ (125 out of 277) in 2018. The increase in number of purse seine sets and purse seine fishing days has mirrored the rise in number of vessels, although the peak in both measures of fishing effort, sets and days, occured a few years earlier

[^0](2011-2013) at around 65,000 (suggesting improvements in efficiency). Purse seine vessels can make more than one set per day, and a day of searching (with no sets made) is counted as a fishing day.

The 2019 purse seine skipjack catch ( $1,708,812 \mathrm{t}-84 \%$ of the total skipjack catch) was $18 \%$ higher than the 2018 catch (Table 4). The 2019 purse seine catch of yellowfin tuna (349,358t) was an $8 \%$ decrease from 2018 (Table 5). The 2019 purse seine catch of bigeye tuna (46,740t) was a $28 \%$ decrease from 2018, and represented $35 \%$ of the total 2019 bigeye catch (Table 6). It is important to note that the purse seine species composition for 2019 will be revised once all observer data for 2019 have been received and processed, and the current estimate should therefore be considered preliminary.

The commercial longline fleet (excluding Vietnamese and Indonesian domestic and Japanese coastal longliners) peaked in size in 1994 at a total of 5,068 vessels (Table 2 and Figure 4). The fleet has steadily declined since then, and totalled 1,669 vessels in 2019. The percentage of longliners flagged to Pacific Island countries has steadily increased from 0 in the mid-1970s to around $30 \%$ in $2017-2019$. While the number of longline vessels has declined over the history of the fishery, a more direct measure of effort hooks fished - has shown a different trend. Total hooks fished in the WCPFC-CA varied around a level of 400 million from the mid 1970s to the late 1990s. Starting in 2001, hooks fished doubled to the 800 million level with the peak occurring in 2012 at 885 million hooks; 2019 was the second highest level on record at 838 million hooks.

The recent longline catch estimates are often uncertain and subject to revision due to delays in reporting. Nevertheless, the bigeye $(72,391 \mathrm{t})$ catch was on par with catches since 2010, while the yellowfin $(107,656 \mathrm{t})$ catch for 2019 was the third highest on record, trailing only the 1980 catch of $125,113 \mathrm{t}$ and 1979 catch of 108,910t.

The pole-and-line fleet has been contracting in size continuously since 1974, when the number of vessels peaked at 798, and totalled just 103 vessels in 2019 (Table 2 and Figure 5). Pole-and-line effort, measured in fishing days, has shown a similar decline, from a high of 88,567 days in 1978 to 10,805 days in 2019.

Skipjack accounts for the majority of the pole-and-line catch (89\%), with yellowfin tuna (10\%) making up the bulk of the remaining catch. The Japanese distant-water and offshore fleet and the Indonesian fleet account for most of the WCPFC-CA pole-and-line catch.

The 2019 troll catch in the WCPFC-CA was the highest catch since 2013, at 8,116 t, most of which was albacore tuna. Skipjack and yellowfin tuna are also taken in significant quantities in tropical small-scale troll fisheries, but most of these catches are reported under "Other gears". Since 2007, New Zealand (average 2,338t catch per year) has had the most consistent effort in the South Pacific albacore troll fishery, with the United States landing a small catch (averaging 376t per year) from the South Pacific.

## 2 Status of tuna stocks

The sections below provide a summary of the recent developments in fisheries for each species, and the results from the most recent stock assessments. A summary of the important biological reference points for the four stocks is provided in Table 9. Bigeye and yellowfin tuna stocks were assessed in 2020, the skipjack tuna stock was assessed in 2019, and the South Pacific albacore stock was assessed in 2018. Due to uncertainty in the fisheries data for the most recent year, data from the year immediately preceding the assessment year is not included in the bigeye, yellowfin and albacore assessments. Thus, the bigeye and yellowfin tuna assessments include data through 2018, while South Pacific albacore currently includes data through 2016. Skipjack, with its shorter lifespan and importance of young fish to the fishery, includes the most recent year of data; thus the 2019 assessment included fisheries data through 2018. Information on the status of other oceanic fisheries resources (e.g. billfishes and sharks) is provided in 4.3 Ecosystem Considerations.

### 2.1 Skipjack tuna

The 2019 WCPFC-CA skipjack catch of 2,045,970t was a record catch (Figure 6 and Table 4). As in recent years, the main contributor to the overall catch of skipjack was that taken in the purse seine fishery ( $1,708,812 \mathrm{t}$ in $2019-84 \%$ of total skipjack catch). The next-highest proportion of the catch was by pole-and-line gear $(153,869 t-8 \%)$. The longline fishery accounted for less than $1 \%$ of the total catch.

The vast majority of skipjack are taken in equatorial areas, and most of the remainder is taken in the seasonal domestic fishery off Japan (Figure 6).

The dominant size of the WCPFC-CA skipjack catch (by weight) typically ranges from 40 cm to 60 cm , corresponding to $1-2^{+}$year-old fish (Figure 6). For pole-and-line, the fish typically range from 40 cm to 55 cm , while skipjack in the domestic fisheries of Indonesia and the Philippines are much smaller $(20-40 \mathrm{~cm})$. In general, skipjack taken in unassociated (free-swimming) schools are larger than those taken in schools associated with Fish Aggregating Devices (FADs).

## Stock assessment

The most recent assessment of skipjack in the WCPO was conducted in 2019, and included data from 1972 to 2018, using an eight region model (Vincent et al. 2019); readers are referred to that document for more details on model configuration and settings. The 2019 assessment included investigaton of alternative regional structures (five and eight regions), growth functions, length composition scalars, tag mixing periods, and levels of steepness in the stock-recruitment relationship. The Scientific Committee (SC) of the Western and Central Pacific Fisheries Commission (WCPFC) agreed to use the eight region model to describe the stock status of skipjack tuna because they considered that it better captured the biology of skipjack tuna. Stock status was determined over an uncertainty grid of 54 models where models with a steepness of 0.65 or 0.95 were down weighted by $20 \%$ and models with a length composition scalar of 50 were also down weighted by $20 \%$, while all other models were given a weighting of 1 . While estimates of fishing mortality for skipjack have increased over time, current fishing mortality rates for skipjack tuna are estimated to be about 0.45 times the level of fishing mortality associated with maximum sustainable yield $\left(F_{M S Y}\right)$. Therefore, overfishing is not occurring (i.e. $\left.F_{\text {recent }}<F_{M S Y}\right)$. Spawning biomass is estimated to be at $44 \%$ of the level predicted in the absence of fishing. Recent spawning biomass levels are estimated to be well above the limit reference point of $20 \%$ of the level predicted in the absence of fishing $\left(S B / S B_{F=0}=0.2\right)$. Overall, the estimated recruitment shows an upward trend over time, but the spawning potential shows a long-term decline. Under status quo fishing conditions, where catch and effort levels are maintained at the average 2016-2018 levels, the stock is projected to have zero probability of dropping below the Limit Reference Point (LRP). A number of diagnostic plots on exploitation history, present status and future projections are shown in Figure 7.

The conclusions of the WCPFC SC at its $15^{t h}$ Regular Session (SC15), which were presented as recommendations to the WCPFC, are outlined below.

- The grid median spawning potential depletion level is $\mathrm{SB}_{\text {recent }} / \mathrm{SB}_{F=0}=0.44$ with a likely range of 0.37 to 0.53 ( $80^{t h}$ percentile). There were no individual models where $\mathrm{SB}_{\text {recent }} / \mathrm{SB}_{F=0}<0.2$, which indicated a zero probability that recent spawning biomass is below the LRP.
- The grid median $\mathrm{F}_{\text {recent }} / \mathrm{F}_{M S Y}$ is 0.45 , with a likely range of 0.34 to 0.60 ( $80^{t h}$ percentile) and no values of $\mathrm{F}_{\text {recent }} / \mathrm{F}_{M S Y}$ in the grid exceed 1. Therefore, there is zero probability that overfishing is occurring.
- The largest uncertainty in the structural uncertainty grid is due to the assumed tag mixing period. SC15 acknowledged that further study is warranted to investigate the uncertainty surrounding the appropriate mixing period for the tagging data.
- The spatial extent of the Japanese pole-and-line fishery has decreased over the time period and the future use of this standardised catch-per-unit-effort (CPUE) index within future stock assessments is uncertain. Therefore, further study of alternative indices of abundance is warranted, such as investigation of standardising the purse seine fishery CPUE and evaluation of the feasibility of conducting fishery independent surveys.

### 2.2 Yellowfin tuna

The WCPC-CA yellowfin catch in 2019, of $696,797 \mathrm{t}$, was lower than the highest value (713,773t), recorded in 2017 (Figure 8 and Table 5). The purse seine catch ( $349,358 \mathrm{t}$ ) decreased by $8 \%$, and the longline catch $(107,656 \mathrm{t})$ increased by $9 \%$, from 2018 levels. The remainder of the yellowfin tuna catch comes from pole-and-line and troll, and the domestic fisheries in Indonesia, Vietnam and the Philippines. The purse seine catch of yellowfin tuna is typically around four times the size of the longline catch.

As with skipjack, most of the yellowfin catch is taken in equatorial areas by large purse seine vessels, and a variety of gears in the Indonesian and Philippines fisheries. The domestic surface fisheries of the

Philippines and Indonesia take large numbers of small yellowfin in the range $20-50 \mathrm{~cm}$ (Figure 8). In the purse seine fishery, greater numbers of smaller yellowfin are caught in log and FAD sets than in unassociated sets. A major proportion (by weight) of the purse seine catch is adult ( $>100 \mathrm{~cm}$ ) yellowfin tuna.

## Stock assessment

The most recent assessment of yellowfin tuna in the WCPO was conducted in 2020 (Vincent et al. 2020) and included data from 1952 to 2018. The 2020 assessment included the incorporation of an index fishery for each of the nine regions, use of additional information on yellowfin growth, and enforcement of mixing periods in the tagging data. The analysis presented the results as a structural uncertainty grid from 72 model runs and those results were equally weighted when developing management advice. Across the range of model runs in this assessment, the key factor influencing estimates of stock status was growth, with the most optimistic stock status estimates those using a growth curve estimated externally from otolith data. Models where growth was estimated from modal size progression were the most pessimistic while a third method, where growth was estimated from both conditional age-at-length and size composition data, was intermediate although closer to the otolith growth curve models. Additional axes of uncertainty in the yellowfin grid included multiple values for steepness in the stock-recruitment relationship, a range of size scalars to weight size frequency data, and an assumed mixing period of either 1 or 2 quarters for tagged fish.

Fishing mortality on both juvenile and adult fish increased has steadily since the early days of the fishery, although juvenile mortality shows signs of leveling off. Current fishing mortality rates for yellowfin tuna, however, are estimated to be below $F_{M S Y}$ in all models, which indicates that overfishing is not occurring. Spawning potential showed a long continuous decline from the 1950s to the 2000s, but appears to have leveled off since around 2010. Recruitment has been variable throughout the assessment period, but somewhat lower in the past three decades relative to the 1950s and 1960s. Recent spawning biomass levels are uniformly ( 72 out of 72 runs) estimated to be above the $\mathrm{SB}_{M S Y}$ level and the LRP of $20 \%$ of the level predicted in the absence of fishing. Under status quo fishing conditions, where effort and catch levels are maintained at the average 2016-2018 levels, the stock is projected to have zero probability of dropping below the LRP. A number of diagnostic plots on exploitation history, present status and future projections are shown in Figure 9.

The conclusions of the WCPFC at its $16^{t h}$ Regular Session (SC16), which were presented as recommendations to the WCPFC in 2020, are outlined below.

- Based on the uncertainty grid adopted by SC16, the WCPO yellowfin tuna spawning biomass is above the biomass LRP and recent F is below $\mathrm{F}_{M S Y}$. The stock is not experiencing overfishing ( $0 \%$ probability $\mathrm{F}_{\text {recent }}>\mathrm{F}_{M S Y}$ ) and is not in an overfished condition ( $0 \%$ probability $\left.\mathrm{SB}_{\text {recent }} / \mathrm{SB}_{F=0}<\mathrm{LRP}\right)$. Additionally, stochastic projections predict there to be no risk of breaching the LRP ( $0 \%$ probability $\mathrm{SB}_{2048} / \mathrm{SB}_{F=0}<\mathrm{LRP}$ ) under average 2016-2018 fishing conditions.
- Levels of fishing mortality and depletion differ between regions, and fishery impact was highest in the tropical region (Regions 3, 4, 7 and 8 in the stock assessment model), mainly due to the purse seine fisheries in the equatorial Pacific and the "other" fisheries within the western Pacific.
- WCPFC could consider reducing fishing mortality on yellowfin, from fisheries that take juveniles, with the goal to increase maximum fishery yields and reduce any further impacts on the spawning potential for this stock in the tropical regions.
- Although the structural uncertainty grid presents a positive indication of stock status, the high level of unresolved conflict amongst the data inputs used in the assessment suggests additional caution may be appropriate when interpreting assessment outcomes to guide management decisions.
- Recommend as a precautionary approach that the fishing mortality on yellowfin tuna stock should not be increased from the level that maintains spawning biomass at 2012-2015 levels until the WCPFC can agree on an appropriate target reference point.

### 2.3 Bigeye tuna

The 2019 WCPFC-CA bigeye tuna catch was $135,442 \mathrm{t}$, which was a drop from the highest value $(181,707 \mathrm{t})$, recorded in 2004. A $18,017 \mathrm{t}$ decrease in purse seine catch and a $3,480 \mathrm{t}$ increase in the longline fishery
(Figure 10 and Table 6) has had the overall effect of a decrease in total bigeye catch relative to 2018. Of the total bigeye catch in $2019,53 \%$ was caught by longline, $35 \%$ by purse seine, and the remainder was distributed across troll, pole and line, and other gears.

The majority of the WCPFC-CA catch is taken in equatorial areas, by both purse seine and longline, but with some longline catch in sub-tropical areas (e.g. east of Japan and off the east coast of Australia) (Figure 10). In the equatorial areas, much of the longline catch is taken in the central Pacific, contiguous with the important traditional bigeye longline area in the eastern Pacific.

As with skipjack and yellowfin tuna, the domestic surface fisheries of the Philippines and Indonesia take large numbers of small bigeye in the range of $20-50 \mathrm{~cm}$. In addition, large numbers of $25-75 \mathrm{~cm}$ bigeye are taken in purse seine fishing on FADs (Figure 10) which, along with the fisheries of the Philippines and Indonesia, account for the bulk of the catch by number. The longline fishery, which lands bigeye mostly above 100 cm , accounts for most of the catch by weight in the WCPFC-CA. This contrasts with large yellowfin tuna, which (in addition to the longline gear) are also taken in significant amounts from unassociated schools in the purse seine fishery and in the Philippines handline fishery. Large bigeye are very rarely taken in the WCPO purse seine fishery, and only a relatively small amount comes from the handline fishery in the Philippines. Bigeye sampled in the longline fishery are predominantly adult fish, with a mean size of approximately 130 cm with most between 80 and 160 cm .

## Stock assessment

The most recent assessment of bigeye tuna in the WCPO was conducted in 2020 (Ducharme-Barth et al. 2020), and included data from 1952 to 2018. This assessment utilised only the new growth estimates first introduced in the 2017 assessment (McKechnie et al. 2017) but also incorporated additional age-at-length information from tag recaptures and implemented the Richards growth model. Additionally, only the $10^{\circ} \mathrm{N}$ spatial structure was considered; an "index fishery" approach with utilisation of spatiotemporal model standardised CPUE indices was implemented for the nine regions, and updates were incorporated for tag data models, purse seine catch estimates, size composition data, and biological parameters for the length-weight relationship and reproductive potential. Management advice was formulated from the results of an uncertainty grid of 24 models that addressed several key model uncertainties. The most influential factor contributing to uncertainty around estimated stock status was the level of data weighting given to the size-frequency data. Assessment outcomes became increasingly optimistic as greater weight was placed on the size-frequency data. Additional model uncertanties addressed in the grid included natural mortality and steepness in the stock-recruitment relationship.

Fishing mortality is estimated to have increased over time, particularly on juveniles over the last two decades, although juvenile mortality shows signs of leveling off. Current fishing mortality rates for bigeye tuna, however, are estimated to be below $F_{M S Y}$ in 21 of the 24 models in the grid, which indicates that overfishing is likely not occurring. Spawning potential showed a long continuous decline from the 1950s to the 2000s, but appears to have leveled off since around 2010. Recruitment has been variable throughout the assessment period, but somewhat higher in the past two decades relative to the 1950s and 1960s. Recent spawning biomass levels are uniformly ( 24 out of 24 runs) estimated to be above both the $\mathrm{SB}_{M S Y}$ level and the LRP of $20 \%$ of the level predicted in the absence of fishing. Under status quo fishing conditions, where effort and catch levels are maintained at the average 2016-2018 levels and relatively positive recent (2007-2016) recruitment patterns continue, the stock is projected to have zero probability of dropping below the LRP. A number of diagnostic plots on exploitation history, present status and future projections are shown in Figure 11.

The conclusions of WCPFC SC16, which were based on placing equal weight on all 24 model runs, were presented as recommendations to the WCPFC, and are outlined below.

- The median catch in the last year of the assessment (2018) was 159,288 t which was greater than the median MSY (140,720t).
- Based on the uncertainty grid, WCPO bigeye tuna spawning biomass is above the biomass LRP and $\mathrm{F}_{\text {recent }}$ is very likely below $\mathrm{F}_{M S Y}$.
- It was concluded that the stock is not overfished ( $0 \%$ probability $\mathrm{SB} / \mathrm{SB}_{F=0}<\mathrm{LRP}$ ) and likely not experiencing overfishing ( $87.5 \%$ probability $\mathrm{F}_{\text {recent }}<\mathrm{F}_{M S Y}$ ).
- Levels of fishing mortality and depletion differ among regions, and that fishery impact was higher in the tropical regions (Regions 3, 4, 7 and 8 in the stock assessment model), with particularly high fishing mortality on juvenile bigeye tuna in these regions. There is also evidence that the overall stock status is buffered with biomass kept at a more elevated level overall by low exploitation in the temperate regions ( $1,2,6$ and 9 ).
- Based on these results, it was recommended as a precautionary approach that the fishing mortality on bigeye tuna stock should not be increased from the level that maintains spawning biomass at 2012-2015 levels until the WCPFC can agree on an appropriate target reference point.

### 2.4 South Pacific albacore tuna

The total South Pacific albacore catch in 2019 ( $69,987 \mathrm{t}$ ) represented a drop from the highest value ( $75,135 \mathrm{t}$ ), recorded in 2017 (Figure 12 and Table 7). Longline fishing has accounted for most of the catch of this stock ( $81 \%$ in the 1990 s, but $96 \%$ in the most recent 10 years). The troll catch, covering a season spanning November to April, has generally been in the range of $3,000-8,000 \mathrm{t}$, however it has averaged $2,674 t$ over the past five years. Note that the albacore assessment presented here is for the albacore stock that occurs south of the equator within the WCPFC-CA and the catch data is presented in Table 7. We also provide the catch data for the albacore stock north of the equator (Table 8, thus the tables together total the numbers in Table 2); the northern albacore stock is presently assessed by the ISC (ALBWG, 2020).

The longline catch is widely distributed across the South Pacific (Figure 12), with the largest catches from the western region. Much of the increase in catch is attributed to that taken by vessels fishing north of latitude $20^{\circ} \mathrm{S}$. The Pacific Island domestic longline fleet catch is restricted to latitudes $10^{\circ}-25^{\circ} \mathrm{S}$. Troll catch is distributed in New Zealand's coastal waters, mainly off the South Island, and along the sub-tropical convergence zone (STCZ). In the past, less than $20 \%$ of the overall South Pacific albacore catch was taken east of $150^{\circ} \mathrm{W}$ but, in the most recent five years, this has increased to over $25 \%$.

The longline fishery takes mainly larger adult albacore, mostly in the narrow size range of $90-105 \mathrm{~cm}$, and the troll fishery takes juvenile fish in the range of $45-80 \mathrm{~cm}$. Juvenile albacore also occasionally appear in the longline catch in more southern latitudes.

## Stock assessment

The most recent stock assessment for South Pacific albacore tuna was undertaken in 2018 (Tremblay-Boyer et al. 2018), and was based on data from 1960 to 2016. This analysis presented the results from a structural uncertainty grid based on 72 model runs for developing management advice. All plausible combinations of the most important axes of uncertainty were included with equal weighting in the grid.

The assessment indicates that fishing mortality has generally been increasing over time, with $F_{\text {recent }}$ (2012-2015 average) estimated to be 0.2 times the fishing mortality that will support the MSY. Across the grid $F_{\text {recent }} / F_{M S Y}$ ranged from 0.06-0.53. This indicates that overfishing is not occurring (Figure 13). Spawning biomass levels are above both the level that will support the MSY ( $S B_{\text {recent }} / S B_{M S Y}=$ 3.3 for the diagnostic case and range 1.45-10.74 across the grid) and the adopted LRP of $0.2 S B_{F=0}$ ( $S B_{\text {recent }} / S B_{F=0}=0.52$ for the median and range $0.32-0.72$ across the grid) indicating that the stock is not overfished. Under status quo fishing conditions, where catch levels are maintained at recent 2019 levels, the stock is projected to have a probability of dropping below the LRP as early as 2020 and this increases to a level of $>30 \%$ by 2048. A number of diagnostic plots on exploitation history, present status and future projections are shown in Figure 13.

The SC also considered an index of economic conditions in the South Pacific albacore fishery (Williams and Reid 2018). This index, which integrates fishing costs, catch rates and fish prices, estimates a strong declining trend in economic conditions, reaching an historical low in 2013. While the economic conditions remain relatively poor, there was a slight recovery in 2017 due to high CPUE for South Pacific albacore.
The conclusions of the WCPFC SC at its $14^{\text {th }}$ Regular Session (SC14), which were based on 72 model runs, were presented as recommendations to the WCPFC, and are outlined below.

- The median spawning biomass depletion level $\left(\mathrm{SB}_{\text {recent }} / \mathrm{SB}_{F=0}\right)$ was 0.52 with an upper and lower bound of 0.37 to 0.63 respectively.
- There was a $0 \%$ probability that the recent spawning biomass had breached the adopted LRP.
- The median fishing impact $\left(\mathrm{F}_{\text {recent }} / \mathrm{F}_{M S Y}\right)$ was 0.2 with a $0 \%$ probability that recent fishing mortality was above $\mathrm{F}_{M S Y}$.
- For several years, SC has noted that any increases in catch or effort in sub-tropical longline fisheries are likely to lead to declines in catch rates in some regions $\left(10^{\circ} \mathrm{S}-30^{\circ} \mathrm{S}\right)$, especially for longline catch of adult albacore, with associated impacts on vessel profitability.
- The assessment results show that, while the stock has exhibited a long-term decline, the stock is not in an overfished state and overfishing is not taking place.

### 2.5 Summary across target tuna stocks

To summarise the most recent stock assessments for the four target tuna stocks, stock status for all four species are plotted together on a single Majuro plot, along with grid model uncertainties (Figure 14). All four are considered to be in a healthy, sustainable status as none are considered to be overfished. Yellowfin, skipjack and albacore are estimated to have a $0 \%$ probability of currently experiencing overfishing, while bigeye is estimated to have a $12.5 \%$ probability. To place these results in context, a summary of stock status for these same four stocks assessed in other ocean basins by the three other tuna Regional Fisheries Management Organizations (RFMOs) are illustrated in Figure 14. As most of the other tuna RFMOs report stock status relative to MSY-based reference points (i.e., $\mathrm{SB} / \mathrm{SB}_{M S Y}$ and $\mathrm{F} / \mathrm{F}_{M S Y}$ ), we based the WCPFC status on the same criteria.

### 2.6 Tuna tagging

Large-scale tagging experiments are required to provide the level of information (fishery exploitation rates and population size) that is necessary to enable stock assessments of tropical tunas in the WCPO. Tagging data have the potential to provide significant information of relevance to stock assessment, either by way of stand-alone analyses or, preferably, through their integration with other data directly in the stock assessment model. Tuna tagging has been a core activity of the Oceanic Fisheries Programme over the last 30 years, with tagging campaigns occurring in the 1970s, 1990s and, most recently, since 2006. This most recent campaign has now tagged and released 452,489 tuna in the equatorial WCPO, including over 1,800 archival tag releases, with 81,591 reported recaptures (Figure 15). A summary of tag releases and recoveries is provided in Table 10.

## 3 Ecosystem and bycatch issues

### 3.1 Catch composition

The tuna fisheries of the WCPO principally target four main tuna species: skipjack; yellowfin; bigeye; and albacore tuna. However, the fisheries also catch a range of other species in association with these. Some of the associated species (bycatch) are of commercial value (by-products), while many others are discarded. There are also incidents of the capture of species of ecological and/or social significance, including marine mammals, sea birds, sea turtles and some species of shark (e.g. whale sharks).

The information concerning the catch composition of the main tuna fisheries in the WCPO comes largely from the various observer programmes operating in the region. Overall, catch (in weight) from unassociated and associated purse seine sets are dominated by tuna species ( $99.7 \%$ and $97.9 \%$, respectively), with anchored FAD sets having a slightly higher bycatch rate ( $99.5 \%$ tuna) than drifting FADs (Figure 16). Historically, associated sets have accounted for the majority of bycatch of finfish and shark species, although there is some variation from year to year due to changes in the proportions of sets by association type (Peatman et al. 2018).

Species composition of the catch has also been estimated for three main longline fisheries operating in the WCPO: the western tropical Pacific (WTP) shallow-setting longline fishery; the WTP deep-setting longline fishery; and the western South Pacific (WSP) albacore fishery. While estimates are uncertain due to the low level of observer coverage, some general conclusions are possible. The main tuna species account for $60.9 \%, 79.8 \%$ and $67.4 \%$ of the total catch (by weight) of the shallow-set, deepset and albacore target longline fisheries respectively (Figure 17). The WTP shallow-set fishery has a higher proportion of non-tuna species in the catch, principally shark and billfish species, while mahi mahi (Coryphaena
hippurus) and opah (Lampris guttatus) represent a significant component of the WSP albacore longline catch. There are also considerable differences in the species composition of the billfish catch in the longline fisheries as follows: the WTP shallow and WSP albacore fisheries catch a higher proportion of surface-orientated species than does the WTP deep-setting fishery. Blue sharks (Prionace glauca) are the most common shark in the deep set fishery (Figure 17).

### 3.2 Species of special interest

A range of conservation and management measures have been introduced by WCPFC to reduce impacts of fisheries on species of special interest, including whale shark (Rhincodon typus), silky shark (Carcharhinus falciformis) and oceanic whitetip shark (Carcharhinus longimanus), sea turtles, whales and seabirds. Spatially and temporally disaggregated summaries of observer bycatch data are publicly available, including observed longline and purse seine effort and interaction rates for species of special interest.

There are limited interactions between the purse seine fishery and protected species, such as whale sharks and manta rays (Mobula birostris) (Figure 16). Historically, some vessels deliberately set around whale sharks associated with tuna schools, but this practice has been prohibited since 2014 in the WCPO. In a very small percentage of cases of free school sets, a whale shark is encountered; in these instances, the whale shark was not seen before the set was made. Observed interaction rates between the purse seine fishery and sea turtles are low ( $<1$ interaction per 100 sets), and interactions with seabirds are very rare.

Interactions with seabirds and marine mammals are very low in all three longline fisheries (although the probability of detecting rare events with low observer coverage means that the estimates of very low interaction rates are very uncertain). Catch of five species of marine turtles has been observed in the equatorial longline fishery, although the observed encounter rate was particularly low, and most of the turtles caught were alive at the time of release.

### 3.3 Catch and status of billfish and sharks

In addition to the main tuna species, annual catch estimates for the WCPO in 2019 are available for the main species of billfish (swordfish (Xiphias gladius) [16,830t], blue marlin (Makaira nigricans) [15,856t], striped marlin (Kajikia audax) [3,637t] and (Istiompax indica) black marlin [1,748t]). For all of these species current catch is around the average for the past decade. Catch of associated species cannot be accurately quantified using logsheet data, but estimates should be possible in the future when longline observer coverage increases. (See Peatman et al. (2018) for more details.) Observer coverage is already sufficiently high to estimate catch of bycatch species for large-scale purse seiners operating in equatorial and tropic waters.

The status of silky and oceanic whitetip sharks is of concern as assessments have shown that stocks are subject to overfishing and, in the case of oceanic whitetip, severely overfished. A WCPFC ban on the use of either shark lines or wire traces in longline sets is in place, which is hoped will reduce the catch of silky and oceanic whitetip sharks. Over the past several years stock assessments have been undertaken for several billfish and shark species, in addition to the main tuna species. The SC recommendations to the WCPFC are broadly outlined below.

- Stabilise stock size or catch/ensure no increase in fishing pressure
- Southwest Pacific swordfish
- Pacific blue marlin
- Reduce catch and/or rebuild the stock and/or reduce effort and/or enhance data collection efforts
- Pacific bluefin tuna
- Southwest Pacific striped marlin
- Western and central north Pacific striped marlin
- Blue shark
- Silky shark
- Oceanic whitetip shark

Two shark (oceanic whitetip and sillky) and two billfish (Southwest Pacific striped marlin and Southwest Pacific swordfish) species have been assessed by SPC staff in recent years (Figure 18). Stock status for these species is based on the Kobe plot, where overfished status is judged relative to spawning stock size at $\mathrm{MSY}^{3}$. There is considerable uncertainty in the estimates of $\mathrm{F} / \mathrm{F}_{M S Y}$ and $\mathrm{SB} / \mathrm{SB}_{M S Y}$ for all four species. Based on the assessment model grid medians, Southwest Pacific striped marlin and oceanic whitetip are likely in an overfished state, while overfishing is likely occurring for silky shark as well as oceanic whitetip.

### 3.4 El Niño Southern Oscillation forecast

One of the major factors influencing the distribution of tuna species, perhaps mostly notably for skipjack, is the El Niño Southern Oscillation (ENSO) (Lehodey et al. 1997). The two extremes of the oscillation, El Niño and La Niña, result in very different distributions of purse seine fishing effort (Figure 19). At the time this report went to press, a medium-strength La Niña event was in progress and forecast to continue across the Pacific from November 2020 to June 2021. Typically, this results in a pooling of warm water in the western Pacific, a relative decrease in sea surface temperature in the eastern Pacific, and a concentration of skipjack in the western Pacific, although we note that every ENSO event differs in its magnitude, range and impact.

### 3.5 Climate change

The Spatial Ecosystem And Population Dynamics (SEAPODYM, Lehodey et al. 2014) modelling framework was used to investigate how climate change could affect the distribution and abundance of skipjack, yellowfin, bigeye tuna and South Pacific albacore, at the Pacific basin scale, and within the EEZs of Pacific Island countries (Senina et al. 2018). The analysis formed two parts, firstly, a model parameterisation phase over the historical period (1980-2010) using an analysis of historic ocean conditions, and then projections of an ensemble of simulations to explore key sources of uncertainty in climate models. Second, five different atmospheric forcing datasets from Earth System models projected under the ("business as usual") Intergovernmental Panel on Climate Change (IPCC) Regional Concentration Pathways 8.5 (RCP8.5) emissions scenario were used to drive physical-biogeochemical models through the $21^{\text {st }}$ century. Additional scenarios were included to explore uncertainty associated with future primary production and dissolved oxygen concentration, as well as possible adaptation through phenotypic plasticity of these tuna species to warmer spawning grounds. The impact of ocean acidification was also included for yellowfin tuna based on results from laboratory experiments.

The historical simulations (Figure 20) reflect key features of the ecology and behaviour of the four tuna species and match the total historical catch in terms of both weight and size frequency distributions. The projections show an eastern shift in the biomass of skipjack and yellowfin tuna over time, with a large and increasing uncertainty for the second half of the century, especially for skipjack tuna. The impact is weaker for bigeye tuna and albacore, which predicts a wider and warmer range of favorable spawning habitat. For albacore, a strong sensitivity to sub-surface oxygen conditions resulted in a very wide range of projected stock sizes. Historical fishing pressure was estimated to have reduced the adult stocks of all four tuna species by $30-55 \%$ by the end of 2010 . The effects of fishing on biomass strongly outweighed the decreases attributed to climate change in the short- to medium-term. Thus, fishing pressure is expected to be the dominant driver of tuna population status until the mid-century. The projected changes in abundance and redistribution of these tuna associated with climate change could have significant implications for the economic development of Pacific Island countries and territories, and the management of tuna resources, at basin scale. In particular, larger proportions of the catch of each species is increasingly expected to be made in international waters.

Table 3: Several indices of fishing effort for the three main gears used in commercial fishing of tuna in the western and central Pacific region, 1960-2019. For vessels, the abbreviations are: DPI - domestic (Pacific Island); DNPI - domestic (non-Pacific Island), DWFN - distant water fishing nation. Longline effort (Mhks) is millions of hooks. Effort totals exclude the following: Japan coastal, Indonesia, Philippine and Vietnam domestic purse seine vessels; Vietnam and Indonesia domestic longline vessels; Japanese coastal and Indonesian domestic vessels for pole-and-line.

|  | Purse seine |  |  |  | Longline |  |  |  | Pole-and-line |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| 2018 | 21,838 | 17,914 | 3,001 | 78 | 341 | 43,172 |
| 2019 | 27,247 | 17,914 | 3,098 | 79 | 775 | 49,113 |

Table 9: BRPs and stock status from the latest stock assessments (assessment year shown in parentheses) for South Pacific albacore, bigeye, skipjack, and yellowfin tunas. All biomasses are in metric tonnes. $S B_{\text {recent }}$ is the average spawning biomass over the last 4 years of the assessment; $S B_{F=0}$ is the average spawning potential (over the recent 10-year period) predicted to occur in the absence of fishing; $M S Y$ is the maximum sustainable yield based on recent patterns of fishing; $F_{\text {recent }} / F_{M S Y}$ is the ratio of recent (using a window one year earlier than for SB ) fishing mortality to that which will support the $M S Y ; S B_{\text {recent }} / S B_{F=0}$ Spawning potential in the recent time period relative to that predicted to occur in the absence of fishing

| BRP | Albacore <br> $(\mathbf{2 0 1 8})$ | Bigeye <br> $\mathbf{( 2 0 2 0 )}$ | Skipjack <br> $\mathbf{( 2 0 1 9 )}$ | Yellowfin <br> $\mathbf{( 2 0 2 0 )}$ |
| :--- | ---: | ---: | ---: | ---: |
| $S B_{\text {recent }}$ | 240,569 | 590,311 | $2,576,701$ | $1,994,655$ |
| $S B_{F=0}$ | 462,633 | $1,353,367$ | $6,299,363$ | $3,603,980$ |
| $M S Y$ | 98,080 | 140,720 | $2,294,024$ | $1,091,200$ |
| $F_{\text {recent }} / F_{M S Y}$ | 0.2 | 0.72 | 0.45 | 0.36 |
| $S B_{\text {recent }} / S B_{F=0}$ | 0.52 | 0.41 | 0.44 | 0.58 |

Table 10: Total of bigeye, skipjack, and yellowfin tuna tagged during the three major tropical tuna tagging projects in the western and central Pacific region. Note: Separate EEZ results are provided for any region with more than 10,000 releases in any single programme; SSAP $=$ Skipjack Survey and Assessment Programme (1977-1981); RTTP $=$ Regional Tuna Tagging Programme (1989-1992); PTTP $=$ Pacific Tuna Tagging Programme (2006-2019).

Figure 1: The WCPO, the eastern Pacific Ocean and the WCPFC-CA boundary. Note: WCPFC-CA is outlined in dark blue. Pacific nation EEZs are outlined in grey and archipelagic waters are shaded turquoise.

Figure 2: Catch (metric tonnes) by gear (top) and species (bottom) for the western and central Pacific region, 1960-2019. Note: data for 2019 are preliminary.

Purse seine catch and effort plots

Figure 3: Time series of catch (top), recent (2015-2019) spatial distribution of catch (middle), and indices of fishing effort, in fleet sizes and number of sets and days (bottom), for the purse seine fishery in the WCPO.

Longline catch and effort plots

Figure 4: Time series of catch (top), recent (2015-2019) spatial distribution of catch (middle), and indices of fishing effort, in fleet sizes and number of hooks fished (bottom), for the longline fishery in the WCPO.

Pole-and-line catch and effort plots

Figure 5: Time series of catch (top), recent (2015-2019) spatial distribution of catch (middle), and indices of fishing effort in fleet sizes and number of days (bottom), for the pole-and-line fishery in the WCPO. Note that vessel numbers and fishing days are not available prior to 1972.

## Skipjack catch data

Figure 6: Time series (top), recent (2015-2019) spatial distribution and assessment regions (middle), and size composition (average for last five years; bottom) of skipjack tuna catch by gear for the WCPO.

Skipjack diagnostic plots

Figure 7: Estimated spawning biomass (top left), recruitment (top right), fishing mortality (middle left) from the diagnostic case; stock status displayed using a Majuro Plot, the large blue point is the diagnostic model and the other points indicate the runs in the sensitivity grid of 54 models (middle right), estimated level of depletion across the grid (bottom left), and 30-year projected depletion based on status quo (2016-2018 catch/effort levels) fishing (bottom right).

Yellowfin catch data

Figure 8: Time series (top), recent (2015-2019) spatial distribution and assessment regions (middle), and size composition (average for last five years, bottom) of yellowfin tuna catch by gear for the WCPO.

## Yellowfin diagnostic plots

Figure 9: Estimated spawning biomass (top left), recruitment (top right), fishing mortality (middle left) from the diagnostic case; stock status displayed using a Majuro Plot, the large blue point is the diagnostic model and the other points indicate the runs in the sensitivity grid of 72 models (middle right), estimated level of depletion across the grid (bottom left), and 30-year projected depletion based on status quo (2016-2018 catch/effort levels) fishing (bottom right).

Bigeye catch data

Figure 10: Time series (top), recent (2015-2019) spatial distribution and assessment regions (middle), and size composition (average for last five years; bottom) of bigeye tuna catch by gear for the WCPO.

Bigeye diagnostic plots

Figure 11: Estimated spawning biomass (top left), recruitment (top right), fishing mortality (middle left) from the diagnostic case; stock status displayed using a Majuro Plot, the large blue point is the diagnostic model and the other points indicate the runs in the sensitivity grid of 24 models (middle right), estimated level of depletion across the grid (bottom left), and 30-year projected depletion, under the "recent recruitment" (2007-2016) assumption, based on status quo (2016-2018 catch/effort levels) fishing (bottom right).

## Albacore catch data

Figure 12: Time series (top), recent (2015-2019) spatial distribution and assessment regions (middle), and size composition (average for last five years, bottom) of South Pacific albacore tuna catch by gear for the WCPO south of the Equator.

## Albacore diagnostic plots

Figure 13: Estimated spawning biomass (top left), recruitment (top right), fishing mortality (middle left) from the diagnostic case; stock status displayed using a Majuro Plot, the large blue point is the diagnostic model and the other points indicate the runs in the sensitivity grid of 72 models (middle right), estimated level of depletion across the grid (bottom left), and 30-year projected depletion based on status quo (2019 catch levels) fishing (bottom right). The depletion target reference point is shown as a green line in the bottom plots.

Figure 14: Majuro plot stock status summary for the four WCPO target tuna stocks (top) and a comparison of stock status for the same four tuna species in the other major ocean basins (bottom). In the Majuro plot, the grid median value is shown as a large dot, the ellipses closely approximate the distribution of values from grid models. Readers are referred to the individual species plots in earlier sections for more precise information on stock status from individual models in the uncertainty grid. The stock status comparison across basins is based on spawning biomass and fishing mortality relative to their MSY values. Data are current as of October 2020 and stock status assessments were obtained directly from documents produced by the responsible tuna RFMO. Catch is average catch over the five most recent years available. The "Unknown/Uncertain" classification was used when the reliability of the reference points was stated to be uncertain or unreliable. Note that North Pacific albacore is co-managed in the Pacific by both WCPFC and the Inter-American Tropical Tuna Commission (IATTC) and is, therefore, included for both organisations with the catch levels reflecting the split between the two convention areas.

Tag releases

Tag recoveries

Figure 15: Tag releases (top) and recaptures (bottom) by species from the recent Pacific Tuna Tagging Programme (PTTP). Release and recovery locations have been aggregated to a $2^{\circ} \times 2^{\circ}$ grid resolution for visual clarity.

Figure 16: Catch composition of the various categories of purse seine fisheries operating in the WCPO based on observer data from the last five years' data. Note: Species comprising less than $0.01 \%$ of the catch are summed in the "other" category.

Figure 17: Catch composition of the various categories of longline fisheries operating in the WCPO based on observer data from the last five years' data.

Figure 18: Kobe plot stock status summary for four species of billfishes and sharks assessed at SPC over the past decade and for which stock status has been determined. Note that this plot differs from that presented for the target tuna (the "Majuro" plot), because the WCPFC has not yet decided on LRPs for these species and therefore MSY-based reference points are used as a default.

El Niño

La Niña

The CFS.v2 ensemble mean (black dashed line) predicts La Niña will continue through 2nd quarter 2021

Figure 19: Illustration of difference in purse seine effort distribution between a strong El Niño (top) and strong La Niña event (middle). A medium strength La Niña event (overall negative sea surface temperature anomaly and westward extension of the "cold tongue" into the western Pacific) is forecasted to occur between the months of December 2020 and June 2021 (source: https://www.cpc.ncep.noaa.gov, forecast date: 16 November 2020).

Figure 20: Envelope of predictions computed from simulation ensembles under IPCC RCP8.5 scenario for the WCPO. The change in total biomass is presented with the average (dotted line) and its envelope bounded by the $5 \%$ and $95 \%$ quantile values of the simulation ensembles. The percentage values represent the change in the mean biomass across runs in the 1990-2010 time window compared with 2090-2100. Modified from Senina et al. (2018).

Pacific Community
BP D5; 98848 Noumea CEDEX

[^0]:    1 The Pacific Community, formerly Secretariat of the Pacific Community.
    2 The ISC North Pacific albacore assessment covers the entire North Pacific, including the waters of the InterAmerican Tropical Tuna Commission Convention Area (IATTC-CA). Catch in the IATTC-CA, which is not included in the tables and figures in this report, has averaged $25 \%$ of the total North Pacific albacore catch over the past five years.

[^1]:    ${ }^{3}$ Because the WCPFC has not agreed upon LRPs for billfish or shark, the Kobe plot, rather than the depletion-based Majuro plot, is the default.
